- *Premise of the study:* The development of microsatellite primers in the endangered species *Dracaena cambodiana* will be the foundation for genetic and conservation studies of *D. cambodiana* and several *Dracaena* species.
- *Methods and Results:* A total of 26 microsatellite markers were developed in Chinese populations of *D. cambodiana*, using the Fast Isolation by AFLP of Sequences Containing Repeats (FIASCO) protocol. Among them, sixteen primer pairs generated polymorphic loci (fourteen of them successfully amplified in other four *Dracaena* species) and ten primer pairs produced monomorphic loci.
- *Conclusions:* These microsatellite markers could be used in the further investigation of population genetics of *D. cambodiana* and other *Dracaena* species.

**Key words:** cross-species amplification; *Dracaena*; endangered species; microsatellite markers.

The genus *Dracaena* includes more than 50 species, which are mainly distributed in tropical and subtropical regions of Asia and Africa. *Dracaena cambodiana* is a narrow-distributed species, which is found in Yunnan, Guangxi, and Hainan provinces in China, Laos, Vietnam, Thailand and Cambodia (Chen and Turland, 2000). In 2001, *D. cambodiana* was listed as an endangered species due to its highly restricted distribution and overexploitation (Fu, 1992). Considering its medicinal, ornamental and ecological values, an appropriate conservation program is urgently needed to prevent further loss of *D. cambodiana*. Therefore, it is essential to develop molecular markers for the population genetic analysis of *D. cambodiana* to provide essential information for the development of a management and conservation strategy.

Due to the reproducibility, multiallelic nature, codominant inheritance, relative abundance and wide genome coverage, microsatellite markers have proven to be highly efficient molecular tools for population genetic studies. In the current study, we (1) developed microsatellite markers for *D. cambodiana* and assessed the polymorphism of these loci in 22 samples collected from 11 geographically distinct populations ( $N = 2$  for each) distributed in Guangxi, Yunnan, and Hainan Provinces in China, and (2) performed cross-amplification tests in four other *Dracaena* species (*D. thalioides*, *D. reflexa*, *D. marginata*, and

*D. gracilis*). Voucher specimens were deposited in Xishuangbanna Tropical Botanical Garden, Chinese Academy of Sciences.

**METHODS AND RESULTS**

Total genomic DNA was extracted from leaf tissues of *D. cambodiana* using a modified cetyltrimethyl ammonium bromide (CTAB) method (Doyle and Doyle, 1987). A dinucleotide-enriched microsatellite genomic library was constructed and screened using a fast isolation by AFLP of sequences containing repeats (FIASCO) protocol with some modifications (Zane et al., 2002). Approximately 250 ng of total genomic DNA was digested with *Mse* I (New England BioLabs, Beverly, MA), and then ligated to the adapters (5' - TACTCAGGACTCAT - 3'/5' - GAC-GATGAGTCTGAG - 3') using T4 DNA ligase (Fermentas, Burlington, Ontario, Canada) and diluted (1:10). Then 5  $\mu$ L digestion-ligation DNA fragments were amplified with 1  $\mu$ L *Mse* I-N primers (5' - GATGAGTCTGAGTAAN - 3') (25  $\mu$ M) in a 20  $\mu$ L volume, using a thermal cycling program of initial denaturation of 3 min at 95°C, followed by 20 cycles of 30 s at 94°C, 1 min at 53°C, 1 min at 72°C, and a final extension at 72°C for 10 min. Approximately 500–1000 ng of amplified DNA was hybridized with 200 pmol of 5'-biotinylated (AG)<sub>15</sub> oligonucleotide in a total volume of 250  $\mu$ L of SSC 4.2  $\times$  and SDS 0.07%. The mixture was incubated at 95°C for 5 min, followed by annealing at 58°C for 2 h and cooled to room temperature. The hybridization mixture was enriched using 600  $\mu$ L of streptavidin-coated beads (Promega, Madison, WI), and three nonstringent and three stringent washes were carried out following Zane et al. (2002). DNA containing repeats were amplified by 30 cycles with *Mse* I-N primers. The polymerase chain reaction (PCR) product was purified with the E.Z.N.A.<sup>1</sup> Gel Extraction Kit (Omega, Bio-Tek, Winooski, VT) and ligated into a pGEM-T plasmid vector (Promega, Madison, WI) and transformed into DH5 $\alpha$  competent cells.

Recombinant clones were detected by PCR amplification using T7/SP6 and (AG)<sub>10</sub> as primers at the following thermal cycling conditions: initial denaturation of 3 min at 95°C, followed by 35 cycles of 30 s at 94°C, 30 s at 55°C, 60 s at 72°C, and a final extension at 72°C for 8 min. A total of 100 clones with foreign inserts and relatively long flanking regions were sequenced using an ABI PRISM 3730 DNA sequence analyzer (Applied Biosystems, Foster City, CA). A total of 74 sequences containing microsatellites were obtained by SSR Hunter 1.3 software hunting (Li and Wan, 2005) and then subjected to primer designing using both PRIMER 3 (Rozen and Skaletsky, 2000) and software OLIGO 6.0 (National Biosciences). About 40 primer pairs were designed and

T<sub>a</sub>, annealing temperature.

used for the subsequent test. These primers are all free of dimer and hairpin structure in 3'-termini, the length of each primer was 18–20 bp, and the value of T<sub>m</sub> are ranged from 48°C to 60°C.

The final SSR-PCR system used in screening was optimized by an orthogonal design experiment, and four levels of five factors (Mg<sup>2+</sup>, dNTP, Primer, Taq polymerase, and DNA template) have been tested separately in this system. The results demonstrated the reaction efficiency was affected by these factors. Based on the results, a stable, productive and reproducible PCR system was obtained: 20 μL system containing 10 ng template DNA, 0.4 μM of forward and reverse primers, 2.5 mM of MgCl<sub>2</sub>, 0.2 mM of dNTPs, 2 μL 10×Taq buffer and 1.0 unit of Taq polymerase (Takara, Dalian, Liaoning, China). Cycling conditions were 94°C for 5 min followed by 30–40 cycles at 94°C for 30 s, 46°C–60°C for 30 s (number of cycles and annealing temperatures were locus-

specific; see Table 1), and 72°C for 1 min, with a final extension step of 8 min at 72°C. The PCR product was then separated on a 8% denaturing polyacrylamide gel and visualized by silver staining. A 25 bp DNA ladder (Promega, Madison, WI) was used as standard for scoring.

A total of 26 of the 40 primers successfully amplified DNA fragments, with 16 showing polymorphism and 10 showing monomorphism. Preliminary population genetics analyses for these polymorphic loci were performed using GENEPOP version 4.0 (Rousset, 2008). The number of alleles per locus (*A*) was 6 to 14 with an average of 9.188, the expected heterozygosity (*H<sub>e</sub>*) ranged from 0.668 to 0.940 and the observed heterozygosity (*H<sub>o</sub>*) varied from 0.333 to 0.875 (Table 2). Eight of the 16 polymorphic loci departed significantly from the Hardy-Weinberg equilibrium (*P* < 0.01), which was due to excess of homozygotes. Analysis of errors using Micro-Checker version 2.2.3 (van Oosterhout et al., 2004)

TABLE 2. Results of initial primer screening in 22 individuals of *Dracaena cambodiana* for 16 polymorphic loci. Number of alleles (A), observed heterozygosity ( $H_o$ ), expected heterozygosity ( $H_E$ ), fixation index (F) and  $P$ -values for the Hardy-Weinberg equilibrium (HWE) test are given for each marker.

\*Indicates the observed heterozygosity is departed significantly from the expected heterozygosity under Hardy-Weinberg equilibrium ( $P < 0.01$ ). Voucher specimens of 11 *Dracaena cambodiana* natural populations: DCJC1568; DCPX1569; DCDF1570; DCSY1571; DCJG1572; DCMY1573; DCZK1574; DCML1575; DCXBL1576; DCMX1577; DCYW1578 were all deposited in Xishuangbanna Tropical Botanical Garden, Chinese Academy of Sciences.

suggested that these loci are likely to contain null alleles. No significant linkage disequilibrium was detected between locus pairs except for locus pair DC136 and DC140, DC435 and DC501, DC435 and DC516, DC003 and DC616, DC448 and DC616 ( $P < 0.01$ ). These 16 loci further investigated for cross-species amplification in other four *Dracaena* (*D. thalioides*, *D. reflexa*, *D. marginata*, *D. gracilis*) species using five individuals for each species. In this test, 14 loci successfully amplified products, and 10 primer pairs among them showed polymorphism in at least one of these four *Dracaena* species (Table 3).

## CONCLUSIONS

A total of 26 primer pairs in *D. cambodiana* could be used to assess the genetic diversity and genetic structure of *Dracaena* species for further evaluation and research.
